

Session (02.01) Interfacing MS Access Database using Java (1)

Dr. Ahmed M. FlShafee

Dr. Ahmed ElShafee, ACU Spring 2016, Practical Applications in CS I

Connecting DB using java code

- Note that the main methods "throws SQLException" public static void main(String[] args) throws SQLException {
- Create a string variable contains the database file path as follows

String database = "jdbc:odbc:Driver={Microsoft Access Driver (*.accdb)};DBQ=D:\\Employees.accdb";

Note that "DBQ=" refers to database file path.

Introduction

- Java uses something called JDBC (Java Database Connectivity) to connect to databases.
- There's a JDBC API, which is the programming part, and a JDBC Driver Manager, which your programs use to connect to the database.
- JDBC allows you to connect to a wide-range of databases (Oracle, MySQL, etc),
- We are going to build a simple MicroSoft Access database ".mdb" or ".accdb" .
- Then access it through java using jdbc driver

Dr. Ahmed ElShafee, ACU Spring 2016, Practical Applications in CS I

 Java provide two classes called "Connection", and "DriverManager" that used in connecting databses as follows

Connection con = DriverManager.getConnection(host, username, password);

Connection conn = DriverManager.getConnection(database, "", "");

- The blanks followed by database parameter is the username and password if required to connect to the database file.
- Now create an object from connection class that returns from connection object created in the last step

Statement s = conn.createStatement();

- Now you are connected to the database
- The next step ot to brows database files tables

Add SQL statements to your java code

 Now we agreed that to display all fields and all records on the table we can use the following statement

SELECT * FROM students

 To execute that statement, you will use the statement object created in the last section to execute the sql statement

String sqlstr= "SELECT * FROM students"; s.execute(sqlstr);

Dr. Ahmed ElShafee, ACU Spring 2016, Practical Applications in CS I

- The ResultSet also has methods you can use to identify a particular column (field) in a row.
- You can do so either by using the name of the column, or by using its index number.
- For our Workers table we set up four columns.
- They had the following names: ID, First_Name, Last_Name, and Job Title.
- The index numbers are therefore 1, 2, 3, 4.

ResultSets

- A **ResultSet** is a way to store and manipulate the records returned from a SQL query.
- **ResultSets** come in three different types.
- The type you use depends on what you want to do with the data:

ResultSet rs = s.getResultSet();

Dr. Ahmed ElShafee, ACU Spring 2016, Practical Applications in CS I

• We set up the ID column to hold Integer values. The method you use to get at integer values in a column is **getInt**:

int id_col = rs.getInt("ID");

• We could use the Index number instead:

int id_col = rs.getInt(1);

- For the other three columns in our database table, we set them up to hold Strings.
- We, therefore, need the getString method:

```
String first_name = rs.getString("First_Name");
```

Or we could use the Index number:

```
String first_name = rs.getString(2);
```

Dr. Ahmed ElShafee, ACU Spring 2016, Practical Applications in CS I

- Now it's the time to fetch the results, which in this case the database table contents, fields X rows
- Create an object from "ResultSet" class, which is responsible of fetching data from database tables

```
ResultSet rs = s.getResultSet();
```

Now get data from records as follows

 Because the ResultSet Cursor is pointing to just before the first record when the data is loaded, we need to use the next method to move to the first row.

• The following code will get the first record from the table:

```
rs.next();
int id_col = rs.getInt("ID");
String first_name = rs.getString("First_Name");
String last_name = rs.getString("Last_Name");
String job = rs.getString("Job_Title");
```

You can add a print line to your code

```
System.out.println(id col + " " + first name + " " + last name + " " + job );
```

Dr. Ahmed ElShafee, ACU Spring 2016, Practical Applications in CS I

Now close the connection and statement to free database

```
s.close(); // Close the statement conn.close(); // Close the database. Its no more required
```
