

# Part (05)

## Introduction to programming with Python

#### Dr. Ahmed M. ElShafee

Dr. Ahmed ElShafee, ACU : Summer 2014, Introduction to CS

## **Programming basics**

- code or source code: The sequence of instructions in a program.
- syntax: The set of legal structures and commands that can be used in a particular programming language.
- output: The messages printed to the user by a program.
- **console**: The text box onto which output is printed.
  - Some source code editors pop up the console as an external window, and others contain their own console window.

## **Compiling and interpreting**

Many languages require you to compile (translate) your program into a form that the machine understands.

Python is instead directly *interpreted* into machine instructions.

#### Expressions

expression: A data value or set of operations to compute a value.

Examples: 1 + 4 \* 3 42

- Arithmetic operators we will use:
  - addition, subtraction/negation, multiplication, division + - \* / 00
    - modulus, a.k.a. remainder
  - exponentiation \* \*

**precedence**: Order in which operations are computed.

\* / % \*\* have a higher precedence than + -

1 + 3 \* 4 **is** 13

Parentheses can be used to force a certain order of evaluation.

(1 + 3) \* 4 **is** 16

٤

#### **Integer division**

When we divide integers with / , the quotient is also an integer.

		3			52
4	)	14	27	)	1425
		12			135
		2			75
					54
					21

- More examples:
  - 35 / 5 **is** 7
  - 84 / 10 **is** 8
  - 156 / 100 **is** 1

The % operator computes the remainder from a division of integers.

#### **Real numbers**

- Python can also manipulate real numbers.
  - **Examples:** 6.022 -15.9997 42.0 2.143e17
- The operators + \* / % \*\* () all work for real numbers.
  - The / produces an exact answer: 15.0 / 2.0 is 7.5
  - The same rules of precedence also apply to real numbers: Evaluate () before \* / % before + -
- When integers and reals are mixed, the result is a real number.
  - Example: 1 / 2.0 is 0.5
  - The conversion occurs on a per-operator basis.

$$\begin{array}{r}
 7 \ / \ 3 \\
 2 \ & 1.2 \\
 2 \ & 1.2 \\
 4 \ & 3 \ / \ 2 \\
 2.4 \ & + \ 3 \ / \ 2 \\
 2.4 \ & + \ 1 \\
 3.4
 \end{array}$$

#### Math commands

#### Python has useful <u>commands</u> for performing calculations.

Command name	Description	Constant	Description
abs( <b>value</b> )	absolute value	е	2.7182818
ceil( <b>value</b> )	rounds up	pi	3.1415926
cos( <b>value</b> )	cosine, in radians		
floor( <b>value</b> )	rounds down		
log( <b>value</b> )	logarithm, base e		
log10( <b>value</b> )	logarithm, base 10		
max( <b>value1, value2</b> )	larger of two values		
<pre>min(value1, value2)</pre>	smaller of two values		
round( <b>value</b> )	nearest whole number		
sin( <b>value</b> )	sine, in radians		
sqrt( <b>value</b> )	square root		

To use many of these commands, you must write the following at the top of your Python program:

from math import \*

## Variables

- variable: A named piece of memory that can store a value.
  - Usage:
    - Compute an expression's result,
    - store that result into a variable,
    - and use that variable later in the program.

#### assignment statement: Stores a value into a variable.

Syntax:

#### name = value

Examples: x = 5

- 5 3.14 Х gpa
- A variable that has been given a value can be used in expressions. x + 4 is 9

Exercise: Evaluate the quadratic equation for a given a, b, and c. ٨

#### print

print : Produces text output on the console.

#### Syntax:

- print "**Message**"
- print **Expression**
- Prints the given text message or expression value on the console, and moves the cursor down to the next line.

#### print Item1, Item2, ..., ItemN

Prints several messages and/or expressions on the same line.

#### Examples:

```
print "Hello, world!"
age = 45
print "You have", 65 - age, "years until retirement"
```

#### Output:

```
Hello, world!
You have 20 years until retirement
```

#### input

input : Reads a number from user input.

• You can assign (store) the result of input into a variable.

```
Example:
age = input("How old are you? ")
print "Your age is", age
print "You have", 65 - age, "years until retirement"
Output:
How old are you? <u>53</u>
Your age is 53
You have 12 years until retirement
```

 Exercise: Write a Python program that prompts the user for his/her amount of money, then reports how many Nintendo Wiis the person can afford, and how much more money he/she will need to afford an additional Wii.

## Repetition (loops) and Selection (if/else)

#### The for loop

#### for loop: Repeats a set of statements over a group of values.

Syntax:

#### for variableName in groupOfValues: statements

- We indent the statements to be repeated with tabs or spaces.
- variableName gives a name to each value, so you can refer to it in the statements.
- groupOfValues can be a range of integers, specified with the range function.
- Example:

```
for x in range(1, 6):
    print x, "squared is", x * x
```

Output:

- 1 squared is 1
- 2 squared is 4
- 3 squared is 9
- 4 squared is 16
- 5 squared is 25

The range function specifies a range of integers:

 range (*start*, *stop*)
 the integers between *start* (inclusive) and *stop* (exclusive)

- It can also accept a third value specifying the change between values.
  - range(start, stop, step) the integers between start (inclusive)

and *stop* (exclusive) by *step* 

```
Example:
```

```
for x in range(5, 0, -1):
    print x
print "Blastoff!"
```

#### Output:

```
5
4
3
2
1
Blastoff!
```

• **Exercise:** How would we print the "99 Bottles of Beer" song?

## **Cumulative loops**

 Some loops incrementally compute a value that is initialized outside the loop. This is sometimes called a *cumulative sum*.

```
sum = 0
for i in range(1, 11):
    sum = sum + (i * i)
print "sum of first 10 squares is", sum
Output:
sum of first 10 squares is 385
```

Exercise: Write a Python program that computes the factorial of an integer.

#### if

- if statement: Executes a group of statements only if a certain condition is true. Otherwise, the statements are skipped.
  - Syntax:
    - if condition: statements
- Example:

```
gpa = 3.4
```

```
if gpa > 2.0:
```

print "Your application is accepted."

#### if/else

if/else statement: Executes one block of statements if a certain condition is True, and a second block of statements if it is False.

#### while

- while **loop**: Executes a group of statements as long as a condition is True.
  - good for indefinite loops (repeat an unknown number of times)
- Syntax: while condition: statements
- Example:

number = 1

while number < 200:

print number,

number = number \* 2

• Output:

1 2 4 8 16 32 64 128

## Logic

#### Many logical expressions use relational operators:

Operator	Meaning	Example	Result
==	equals	1 + 1 == 2	True
! =	does not equal	3.2 != 2.5	True
<	less than	10 < 5	False
>	greater than	10 > 5	True
<=	less than or equal to	126 <= 100	False
>=	greater than or equal to	5.0 >= 5.0	True

Logical expressions can be combined with *logical operators*:

Operator	Example	Result
and	9 != 6 and 2 < 3	True
or	2 == 3  or  -1 < 5	True
not	not 7 > 0	False

Exercise: Write code to display and count the factors of a number.

## **Text and File Processing**

## Strings

- **string**: A sequence of text characters in a program.
  - Strings start and end with quotation mark " or apostrophe ' characters.
  - Examples:

```
"hello"
"This is a string"
"This, too, is a string. It can be very long!"
```

 A string may not span across multiple lines or contain a " character. "This is not a legal String."

"This is not a "legal" String either."

- A string can represent characters by preceding them with a backslash.
  - \t tab character
  - \n new line character
  - \" quotation mark character
  - \\ backslash character
  - Example: "Hello\tthere\nHow are you?"

#### Indexes

- Characters in a string are numbered with *indexes* starting at 0:
  - Example:

name = "P. Diddy"

index	0	1	2	3	4	5	6	7
character	Ρ	•		D	i	d	d	У

- Accessing an individual character of a string: *variableName* [ *index* ]
  - Example:

print name, "starts with", name[0]

#### Output:

P. Diddy starts with P

## **String properties**

- len(string)
- str.lower(string)
- str.upper(string)

- number of characters in a string (including spaces)
- lowercase version of a string
- uppercase version of a string

```
■ Example:
name = "Martin Douglas Stepp"
length = len(name)
big_name = str.upper(name)
print big_name, "has", length, "characters"
```

Output:

MARTIN DOUGLAS STEPP has 20 characters

#### raw\_input

raw\_input : Reads a string of text from user input.

Example: name = raw\_input("Howdy, pardner. What's yer name? ") print name, "... what a silly name!" Output:

```
Howdy, pardner. What's yer name? Paris Hilton
Paris Hilton ... what a silly name!
```

#### **Text processing**

#### text processing: Examining, editing, formatting text.

- often uses loops that examine the characters of a string one by one
- A for loop can examine each character in a string in sequence.
  - Example:

```
for c in "booyah":
    print c
```

```
Output:
```

b o o y a h

## **Strings and numbers**

- ord(text) converts a string into a number.
  - Example: ord("a") is 97, ord("b") is 98, ...
  - Characters map to numbers using standardized mappings such as ASCII and Unicode.
- chr(number) converts a number into a string.
  - Example: chr(99) is "c"

- Exercise: Write a program that performs a rotation cypher.
  - e.g. "Attack" when rotated by 1 becomes "buubdl"

## File processing

Many programs handle data, which often comes from files.

Reading the entire contents of a file:

```
variableName = open("filename").read()
```

Example: file text = open("bankaccount.txt").read()

## Line-by-line processing

Reading a file line-by-line:

```
for line in open("filename").readlines():
    statements
```

```
Example:
count = 0
for line in open("bankaccount.txt").readlines():
    count = count + 1
print "The file contains", count, "lines."
```

Exercise: Write a program to process a file of DNA text, such as: ATGCAATTGCTCGATTAG

Count the percent of C+G present in the DNA.

#### Graphics

## DrawingPanel

To create a window, create a drawingpanel and its graphical pen, which we'll call g :

```
from drawingpanel import *
panel = drawingpanel(width, height)
g = panel.get_graphics()
... (draw shapes here) ...
```

```
panel.mainloop()
```

- $\hfill\blacksquare$  The window has nothing on it, but we can draw shapes and lines on it by sending commands to g .
  - Example:

```
g.create_rectangle(10, 30, 60, 35)
g.create_oval(80, 40, 50, 70)
g.create_line(50, 50, 90, 70)
```

## **Graphical commands**

Command	Description
g.create_line( <b>x1, y1, x2, y2</b> )	a line between ( <b>x1</b> , <b>y1</b> ), ( <b>x2</b> , <b>y2</b> )
g.create_oval( <b>x1, y1, x2, y2</b> )	the largest oval that fits in a box with top-left corner at ( <b>x1</b> , <b>y1</b> ) and bottom-left corner at ( <b>x2</b> , <b>y2</b> )
g.create_rectangle( <b>x1, y1, x2, y2</b> )	the rectangle with top-left corner at ( <b>x1</b> , <b>y1</b> ), bottom-left at ( <b>x2</b> , <b>y2</b> )
g.create_text( <b>x</b> , y, text=" <b>text</b> ")	the given <b>text</b> at ( <b>x</b> , <b>y</b> )

The above commands can accept optional outline and fill colors. g.create\_rectangle(10, 40, 22, 65, fill="red", outline="blue")

The coordinate system is y-inverted:

## **Drawing with loops**

- We can draw many repetitions of the same item at different x/y positions with for loops.
  - The x or y assignment expression contains the loop counter, i, so that in each pass of the loop, when i changes, so does x or y.

```
from drawingpanel import *
window = drawingpanel(500, 400)
g = window.get_graphics()
for i in range(1, 11):
    x = 100 + 20 * i
    y = 5 + 20 * i
    g.create_oval(x, y, x + 50, y + 50, fill="red")
```

window.mainloop()

Exercise: Draw the figure at right.

Thanks,.. See you next week (ISA),...
